# Atmosphere feedbacks during ENSO

## Multi-model and sensitivity studies show that AGCM has a dominant role

(e.g. Schneider 2002, Guilyardi et al. 2004, Kim et al. 2008, Neale et al. 2008, Sun et al. 2008, 2010...)

Two types of feedbacks:

Dynamical: Bjerknes feedback  $\mu$

Heat flux feedback (response)  $\alpha$

This talk: what for  $\mu$  and  $\alpha$  in model ENSO diversity ?

Guilyardi et al. (2004)

# Evaluating the Bjerknes feedback $\mu$

Niño 4 TauX anomaly

Niño 3 SST anomaly

Seasonal evolution of  $\mu$

- Monthly variability = measure of seasonal phase lock
- Bjerknes amplification stronger in July-December
- Obs. values of  $\mu$  vary from 10 to 15 ( $10^{-3} \text{ N.m}^{-2}/\text{C}$ )

# Evaluating the heat flux feedback $\alpha$

Niño 3 Heat Flux anomaly

Niño 3 SST anomaly

- Defined as slope of heat flux  $QA = F(\text{SSTA})$
- $\alpha$  varies from  $-10 \text{ W.m}^{-2}/\text{C}$  to  $-40 \text{ W.m}^{-2}/\text{C}$
- Damping stronger in January-May

# Impact of atmosphere convection scheme on ENSO

Observations  
(0.9 C) - HadiSST1.1

IPSL (KE)  
Kerry Emanuel  
(1.0 C) - in IPCC

IPSL/Tiedke (TI)  
(0.3 C) – old scheme

IPSL-CM4 model

ENSO has  
disappeared !

What role for  $\alpha$  and  $\mu$  ?

# Impact of deep convection scheme on atmosphere feedbacks during ENSO

|     | $\mu$                                                | $\alpha$                                                            | El Niño<br>Amplitude |                        |
|-----|------------------------------------------------------|---------------------------------------------------------------------|----------------------|------------------------|
| Obs | ~10                                                  | -18                                                                 | 0.9                  |                        |
| KE  | 4                                                    | -5                                                                  | 1.0                  | → Error compensation ! |
| TI  | 4                                                    | -20                                                                 | 0.3                  |                        |
|     | $10^{-3} \text{ N.m}^{-2}/\text{C}$                  | $\text{W.m}^{-2}/\text{C}$                                          | $^{\circ}\text{C}$   |                        |
|     | ↓                                                    | ↓                                                                   |                      |                        |
|     | Too weak (can improve<br>with atmosphere resolution) | Due to shortwave feedback difference<br>(convection stronger in TI) |                      |                        |

→ Need to get the right ENSO amplitude for the right reasons !

# Seasonal evolution of feedbacks

-25 W.m<sup>-2</sup>/C

$\Leftrightarrow$

1°C/month in  
SST cooling !!!  
(MXL 50 m,  
SSTA of 2°C)

- Shortwave HF feedback  $\alpha_{sw}$  in second half of year explains most of the difference

## $\alpha_{sw}$ feedback distribution

- *JASOND point-wise regression of SHF anomaly vs. SSTA (correl. less than 0.2 blanked out)*
- Negative feedback (blue) = convective regime
- Positive feedback (red/orange) = subsidence regime
- ERA40 has large errors in East Pacific (Cronin et al. 2006)
- AMIP KE closer to ISCCP
- AMIP TI has too strong convection
- In KE, subsidence/+ve  $\alpha_{sw}$  invades central Pacific
- In TI, convection/-ve  $\alpha_{sw}$  invades east Pacific
- Coupled vs. forced (Yu & Kirtman 2007)

# Can we suppress ENSO in KE ?

- Perform KE run with increased  $\alpha_{sw}$ 
  - Interannual Flux Correction:
    - $SHF_o = SHF_{sc}^{KE} + \alpha_{sw}^{mod} (SST_o - SST_{sc}^{KE})$
    - $\alpha_{sw}^{mod} = -15 \text{ W.m}^{-2}$
  - Mean state (SC) unchanged

# Can we suppress ENSO in KE ?

- Perform KE run with increased  $\alpha_{sw}$ 
  - Interannual Flux Correction:
    - $SHF_o = SHF_{sc}^{KE} + \alpha_{sw}^{mod} (SST_o - SST_{sc}^{KE})$
    - $\alpha_{sw}^{mod} = -15 \text{ W.m}^{-2}$
  - Mean state (SC) unchanged

ENSO gone as well !

# $\mu$ and $\alpha$ in the CMIP3 coupled simulations

- Models underestimate both  $\mu$  and  $\alpha$  with respect to the observed values => error compensation.

# ENSO amplitude vs. $\alpha$

Models with stronger heat flux damping (more negative  $\alpha$ ) tend to exhibit weaker ENSO, and vice versa  
(corr = 0.61, sig. at 0.05 level).

- Suggests that  $\alpha$  is an important contributor to model ENSO amplitude biases.
- On the other hand, no relationship found between  $\mu$  and ENSO amplitude.
- Supported by Kim and Jin (2010,b), who apply BJ index to CMIP3 GCMs to show:

the "diversity in ENSO stability [amplitude] is attributable to the large model-to-model difference in the **sensitivity of the oceanic response to wind forcing** and in the **atmospheric thermodynamic response to a SST anomaly**".

# Breaking down the $\alpha$ feedback

- The net  $\alpha$  feedback is dominated by the SW and LH components
- Main cause of  $\alpha$  biases is the SW component,  $\alpha_{\text{SW}}$  (8 models have positive  $\alpha_{\text{SW}}$ )

# AMIP heat flux components

- As in the coupled runs, the LH and SW feedbacks dominate.
- Improvements in  $\alpha_{\text{SW}}$  explain most of the overall  $\alpha$  improvement, but  $\alpha_{\text{SW}}$  biases still dominate.

$\alpha$  Components, Niño 3 ( $Wm^{-2}C^{-1}$ )

AMIP

Coupled

ts

e.  
ement, but  $\alpha_{sw}$  biases

# The $\alpha_{SW}$ Feedback Mechanism: Clouds

- No CFMIP in CMIP3 so we use TOA cloud radiative forcing (CRF) to infer cloud details:

$$CRF_{SW} = SW_{\text{clear-sky}} - SW_{\text{all-sky}}$$

$$CRF_{LW} = LW_{\text{clear-sky}} - LW_{\text{all-sky}}$$

**Niño 3r**  
5°N – 5°S  
120°W – 90°W

## Cloud radiative forcing of low clouds in ISCCP

- $CRF_{SW}$  typically -40 to -60  $Wm^{-2}$  (depends on optical thickness)
- Low clouds have small positive  $CRF_{LW} < 10 Wm^{-2}$
- Blue/green points = JASON/D

$CRF_{SW}$

$CRF_{LW}$

ISCCP low cloud amount

# The $\alpha_{SW}$ Feedback Mechanism: Clouds

- Low clouds positioned close to y-axis (low  $CRF_{LW}$ )
- Models have errors in both low cloud amount and optical thickness
- **HadGEM1**: low clouds too optically thick? Explains weaker  $\alpha_{SW}$ ?
- **CNRM**: bias towards higher clouds? Explains strong negative  $\alpha_{SW}$ ?
- **MRI**: bias towards lower clouds? Explains positive  $\alpha_{SW}$ ?

# A simple framework for unravelling $\alpha_{SW}$

$$\frac{\partial SW}{\partial SST} = \underbrace{\frac{\partial \omega_{500}}{\partial SST}}_{(1)} \times \underbrace{\frac{\partial TCC}{\partial \omega_{500}}}_{(2)} \times \underbrace{\frac{\partial SW}{\partial TCC}}_{(3)} \approx \alpha_{SW}$$

Correlations between the model  $\alpha_{SW}$  values and each response:

|                | (1) $\delta\omega_{500}/\delta SST$ | (2) $\delta TCC/\delta\omega_{500}$ | (3) $\delta SW/\delta TCC$ |
|----------------|-------------------------------------|-------------------------------------|----------------------------|
| <b>AMIP</b>    | -0.12                               | <b>0.84</b>                         | 0.50                       |
| <b>Coupled</b> | -0.10                               | <b>0.82</b>                         | -0.19                      |

AMIP

- $\text{corr}(\alpha_{SW}, \delta TCC/\delta\omega_{500} \times \delta SW/\delta TCC) = -0.97$
- Cloud properties in eastern Pacific are the main source of AMIP  $\alpha_{SW}$  errors

Coupled

- $\delta\omega_{500}/\delta SST$  main cause of Coupled/AMIP difference

# A simple framework for unravelling $\alpha_{SW}$

$$\frac{\partial SW}{\partial SST} = \underbrace{\frac{\partial \omega_{500}}{\partial SST}}_{(1)} \times \underbrace{\frac{\partial TCC}{\partial \omega_{500}}}_{(2)} \times \underbrace{\frac{\partial SW}{\partial TCC}}_{(3)} \approx \alpha_{SW}$$

Correlations between the model  $\alpha_{SW}$  values and each response:

|                | (1) $\delta\omega_{500}/\delta SST$ | (2) $\delta TCC/\delta\omega_{500}$ | (3) $\delta SW/\delta TCC$ |
|----------------|-------------------------------------|-------------------------------------|----------------------------|

| <b>Coupled</b> | -0.10                               | <b>0.82</b>                         | -0.19                      |

AMIP

- $\text{corr}(\alpha_{SW}, \delta TCC/\delta\omega_{500} \times \delta SW/\delta TCC) = -0.97$
- Cloud properties in eastern Pacific are the main source of AMIP  $\alpha_{SW}$  errors

Coupled

- $\delta\omega_{500}/\delta SST$  main cause of Coupled/AMIP difference

# Summary

- ENSO in IPCC-class GCMs:
  - significant progress in CMIP3 vs. previous generations
  - still major errors (too much diversity, structure, timing,...)

# Summary

- ENSO in IPCC-class GCMs:
  - significant progress in CMIP3 vs. previous generations
  - still major errors (too much diversity, structure, timing,...)
- Atmosphere GCM is a dominant contributor:
  - Dynamical +ve ( $\mu$ ) and heat flux -ve ( $\alpha$ ) feedbacks both likely to control ENSO properties in CGCMs
  - Both feedbacks are usually too weak in models
  - Convection scheme has direct impact on  $\alpha_{sw}$  (TI vs. KE)
  - This is already seen in AMIP mode
  - Role of clouds dominant (EUCLIPSE)

# Summary

- ENSO in IPCC-class GCMs:
  - significant progress in CMIP3 vs. previous generations
  - still major errors (too much diversity, structure, timing,...)
- Atmosphere GCM is a dominant contributor:
  - Dynamical +ve ( $\mu$ ) and heat flux -ve ( $\alpha$ ) feedbacks both likely to control ENSO properties in CGCMs
  - Both feedbacks are usually too weak in models
  - Convection scheme has direct impact on  $\alpha_{SW}$  (TI vs. KE)
  - This is already seen in AMIP mode
  - Role of clouds dominant (EUCLIPSE)
- $\alpha_{SW}$  analysis provides a framework to attribute errors

$$\frac{\partial SW}{\partial SST} = \frac{\partial \omega_{500}}{\partial SST} \times \underbrace{\frac{\partial TCC}{\partial \omega_{500}} \times \frac{\partial SW}{\partial TCC}}_{\text{AMIP}} \approx \alpha_{SW}$$

- Caveat on non-local / non-linear part

**Coupled**

# EUCLIPSE analysis plans for WP2

- Is ENSO better simulated in CMIP5 models (CLIVAR metrics)?
- Can we link improvement (if any) of modeled ENSO with atmospheric feedbacks representation? And can we understand the reason why?
  - Understand cloud-related mechanisms vs. dynamical
    - e.g.  $\alpha_{sw}$ : understand the 3-way relationship: SST – Large-Scale Dynamics ( $\omega_{500}$ ) – Clouds (low-mid-high)
  - Explore links with other biases (double ITCZ, MJO errors,...)
  - Role of scale interactions, non-linearities (annual cycle, MJO, cyclones, convection threshold...)

# Shortwave flux feedback in IPSL-CM5A and IPSL-CM5B

OAFlux ( $\alpha = -18 \text{ Wm}^{-2}\text{C}^{-1}$ )

IPSL-CM5A-LR ( $\alpha = -5 \text{ Wm}^{-2}\text{C}^{-1}$ )

IPSL-CM5A has a stronger positive  $\alpha_{\text{sw}}$  than any of the CMIP3 runs.

IPSL-CM5B-LR ( $\alpha = -10 \text{ Wm}^{-2}\text{C}^{-1}$ )

IPSL-CM5B-MR ( $\alpha = -14 \text{ Wm}^{-2}\text{C}^{-1}$ )

IPSL-CM5B (new atmosphere physics) shows considerable improvements

IPSL-CM4:  $\alpha = -7 \text{ Wm}^{-2}\text{C}^{-1}$

$\alpha_{\text{sw}} = +3.5 \text{ Wm}^{-2}\text{C}^{-1}$

# Mean seasonal cycle at Equator

- Wind stress (shading)
- SST (solid contours)
- Precipitation (3 and 8 mm/day dashed)

- AMIP KE performs rather well
- Convection in AMIP TI too strong and triggered early
- Biases amplified in coupled mode
- Semi-annual cycle in TI
- Similar errors than for ENSO
